Bag valve mask ventilation

April, 2016

The ability to oxygenate and ventilate the critically ill patient with bag valve mask (BVM) ventilation is a life-saving skill. BVM ventilation assists in providing oxygenation and ventilation until a more definitive airway can be established.

The terminology used to describe providing ventilation to an apnoeic patient is referred to as intermittent positive pressure ventilation (IPPV).

Indications

- Acute respiratory distress, hypoventilation or arrest requiring positive pressure ventilation.

Contraindications

- Spontaneously breathing patients with adequate tidal volume and an appropriate respiratory rate.

Complications

- Gastric inflation
- Pulmonary barotrauma
- Undesirable cardiovascular effects such as hypotension, secondary to caval compression.

Procedure – Bag valve mask ventilation

1. Determine the need for IPPV.
2. Continuously ensure the patient has a patent airway, apply basic airway management procedures and progress to advanced airway techniques when appropriate.
3. Ensure appropriate positioning of the patient.
4. Test that the resuscitator functions properly:
 - With no fresh gas flowing into the self-expanding squeeze bag and with the patient port (mask) completely occluded, compress the squeeze bag and feel for resistance.
 - With the patient port open, compress the squeeze bag and visually inspect for opening of the patient valve.
5. If Positive End Expiratory Pressure (PEEP) is required, remove the expiratory flow diverter cap and connect the PEEP valve firmly to the expiratory flow diverter.
6. Connect the oxygen supply tubing to an oxygen source and adjust the oxygen flow to 15 L/min.
7. Ensure the air cushion on the mask is adequately inflated to achieve a tight seal on the face during resuscitation.
8. If inflation is required, inflate via the inflation port on the mask using a syringe.
9. Create an effective seal between the cuffed mask and the face.

Remove expiratory flow diverter cap and connect PEEP valve to expiratory flow diverter

Procedure – Bag valve mask ventilation

10. Gently compress the squeeze bag to deliver an appropriate tidal volume and observe the chest rise to confirm ventilation.
11. Release the pressure on the squeeze bag to allow passive exhalation and re-expansion of the bag.
12. During ventilation, check for:
 - signs of cyanosis
 - adequacy of ventilation
 - airway pressure
 - correct functioning of all valves and tubing
 - continuous supply of oxygen to the resuscitator and inflation of the reservoir bag.

+ Additional information

- The pressure release valve plug is not to be inserted under any circumstances.
- The expiratory flow diverter cap is only to be removed when a PEEP valve is required to be connected (CCPs only)
- Use extreme caution if ventilating asthmatics or neonates.^[1,2]
- Creating an effective seal between the mask and face is a skill requiring practice and revision to ensure competency.^[3]
- For patients not requiring positive pressure ventilation, however requiring oxygen, the application of an appropriate oxygen mask is required.

+ Additional information *(cont.)*

- The QAS supplies **three** sizes of Mayo Healthcare disposable *(single use only)* resuscitators.

SPECIFICATIONS			
	Body mass range	Volume (bag/stroke)	Delivery Pressure Limit
Adult	> 23 kg	1500/1200 mL	60 (\pm 10) cm H ₂ O
Paediatric	6.5 – 23 kg	550/330 mL	40 (\pm 5) cm H ₂ O
Neonatal	< 6.5 kg	300/160 mL	40 (\pm 5) cm H ₂ O

- Mayo Healthcare disposable resuscitators *(all sizes)* are individually packaged in a resealable zip-lock bag and contain the following:
 - Air cushion mask
 - Expiratory flow diverter with removable cap (for application of PEEP)
 - Squeeze bag
 - Intake/reservoir valve
 - Oxygen tubing

Adult

Child

Neonatal
